What Exactly is a Molecular Formula?

Before we jump into the nitty-gritty of worksheets, let's get crystal clear on what a molecular formula actually represents. In simple terms, a **molecular formula** is a symbolic representation of a molecule that shows the exact number and types of atoms present in one molecule of a compound. It's like a recipe for a single molecule. For example, the molecular formula for glucose is $\text{C}_6\text{H}_{12}\text{O}_6$. This tells us that one molecule of glucose contains 6 carbon atoms, 12 hydrogen atoms, and 6 oxygen atoms. It doesn't tell us how these atoms are arranged (that's where structural formulas come in), but it gives us the fundamental building blocks.

Why are Molecular Formulas Important?

The significance of molecular formulas extends far beyond simply naming compounds. They are crucial for: **Identifying Compounds.** Each unique molecular formula corresponds to a specific chemical compound.

This allows chemists to unequivocally identify substances. * **Calculating Molar Mass:** Knowing the molecular formula allows you to calculate the molar mass of a compound, which is essential for stoichiometry calculations (predicting the amounts of reactants and products in chemical reactions). * **Understanding Chemical Reactions:** By understanding the molecular formulas of reactants and products, you can balance chemical equations, a fundamental skill in chemistry. * **Drug Discovery and Development:** In pharmaceuticals, precise molecular formulas are critical for designing and synthesizing effective and safe drugs. Even a slight alteration can change a drug's efficacy or introduce toxicity. * **Materials Science:** The properties of materials, from plastics to alloys, are directly related to their molecular composition. Understanding molecular formulas helps in designing materials with specific characteristics. * **Environmental Science:** Tracking pollutants and understanding chemical processes in the environment often relies on identifying and quantifying compounds using their molecular formulas.

Types of Chemical Formulas: A Quick Refresher

While we're focusing on molecular formulas, it's helpful to briefly touch upon other types of chemical formulas to avoid confusion: * **Empirical Formula:** This is the simplest whole-number ratio of atoms of each element in a compound. For example, the empirical formula for glucose ($C_6H_{12}O_6$) is CH_2O . It provides the relative number of atoms but not the actual number in a molecule. * **Structural Formula:** This formula shows the arrangement of atoms and the bonds between them within a molecule. It gives us a 3D or 2D representation of the molecule's structure. * **Condensed Structural Formula:** This is a shorthand way of writing a structural formula, often omitting explicit bonds and showing functional

groups in a more compact form. Today, our spotlight is firmly on the **molecular formula** and how to master it with our practice worksheet.

Determining Molecular Formulas from Empirical Formulas and Molar Mass

Now, let's tackle a slightly more advanced concept. Sometimes, you might know the **empirical formula** (the simplest whole-number ratio of atoms) and the **molar mass** of a compound. You can use this information to find the actual **molecular formula**. Here's how: 1.

Calculate the empirical formula mass: This is the sum of the atomic masses of the atoms in the empirical formula. 2. **Find the ratio:** Divide the given molar mass of the compound by the empirical formula mass. This will give you a whole number (or very close to it). 3. **Multiply the empirical formula:** Multiply the subscripts in the empirical formula by the ratio you found in step 2. This will give you the molecular formula. Let's

practice this with a few examples.

Common Pitfalls and How to Avoid Them

Confusing Empirical and Molecular Formulas: Remember, the empirical formula is the *simplest ratio*, while the molecular formula is the

actual number of atoms. They are not always the same. * **Incorrect Atomic Masses:** When calculating molar masses, ensure you're using accurate atomic masses from the periodic table. Small errors can lead to incorrect ratios. * **Rounding Errors:** When calculating the ratio between molar mass and empirical formula mass, you should get a whole number. If you get something like 2.99 or 3.01, it's usually safe to round to the nearest whole number (3 in this case). However, if the number is significantly off (e.g., 3.5), you might have made a calculation error. * **Misinterpreting Chemical Names:** Always double-check that you're translating chemical names into the correct atom counts. Sometimes names can be tricky!

Taking Your Understanding Further

This worksheet is a great starting point, but chemistry is a vast and fascinating field. To deepen your understanding of molecular formulas: * **Practice, Practice, Practice:** The more you work with molecular formulas, the more intuitive they will become. Look for additional practice problems online or in your chemistry textbook. * **Explore Structural Formulas:** Once you're comfortable with molecular formulas, delve into structural formulas. This will give you a visual understanding of how molecules are put together. * **Learn about Ions and Ionic Compounds:** While this worksheet focused on molecules (covalent compounds), understanding ions and how they form ionic compounds is another crucial aspect of chemical nomenclature and formula writing. * **Use Online Resources:** Many excellent websites offer interactive quizzes, video tutorials, and detailed explanations of chemical concepts.

Mastering Molecular Formulas: Your Comprehensive Guide and Essential Worksheet with Answers

Understanding molecular formulas is a cornerstone of chemistry, laying the groundwork for comprehending chemical reactions, compound properties, and stoichiometry. For students grappling with this fundamental concept, a well-structured molecular formula worksheet with answers can be an invaluable tool. This article delves deep into the world of molecular formulas, explaining their significance, how they are derived, and providing a detailed walkthrough of a comprehensive worksheet designed to solidify your understanding. We'll also explore the nuances of

empirical formulas and their relationship to molecular formulas, crucial for accurate chemical representation.

What is a Molecular Formula? Unpacking the Basics

At its core, a molecular formula is a representation of a chemical compound that indicates the exact number of atoms of each element present in a single molecule of that substance. Unlike empirical formulas, which show the simplest whole-number ratio of atoms, molecular formulas provide the true composition. For instance, the molecular formula for water is H_2O , clearly stating that each molecule contains two hydrogen atoms and one oxygen atom. In contrast, glucose has the molecular formula $\text{C}_6\text{H}_{12}\text{O}_6$, but its empirical formula is CH_2O , representing the simplest ratio.

The molecular formula is essential for:

1. **Accurate Identification:** It uniquely identifies a specific molecule, distinguishing it from others with similar elemental compositions but different arrangements of atoms (isomers).
2. **Stoichiometric Calculations:** It's the basis for calculating molar masses, determining reactant and product quantities in chemical reactions, and understanding reaction yields.
3. **Predicting Properties:** While not solely determinative, the molecular formula, along with structural information, helps predict a compound's physical and chemical properties.
4. **Understanding Bonding:** It implicitly suggests the types of bonds present within a molecule.

From Empirical to Molecular: The Crucial Link

Often, the journey to determining a molecular formula begins with its empirical formula. An empirical formula is derived from experimental data, typically elemental analysis, which gives the percentage composition by mass of each element in a compound. To convert an empirical formula to a molecular formula, we need one additional piece of information: the molecular weight (or molar mass) of the compound. This molecular weight is usually provided in the problem or determined experimentally.

The relationship is straightforward: the molecular formula is an integer multiple of the empirical formula. This multiple, often denoted by 'n', can be calculated using the formula:

$$n = (\text{Molecular Weight}) / (\text{Empirical Formula Weight})$$

Once 'n' is determined, each subscript in the empirical formula is multiplied by 'n' to obtain the molecular formula.

Navigating the Molecular Formula Worksheet: A Step-by-Step Approach

A well-designed molecular formula worksheet will present problems that require students to apply these concepts. Let's break down the typical steps involved in solving such problems, which you'll find reinforced in our provided worksheet with answers.

Step 1: Determine the Empirical Formula from Percentage Composition

This is the foundational step. You'll be given the percentage by mass of each element in a compound. Assume you have a 100-gram sample to

easily convert percentages to grams. Then, convert the mass of each element to moles using its atomic weight from the periodic table. Finally, find the simplest whole-number ratio of moles by dividing each molar quantity by the smallest molar quantity. If the resulting ratios are not whole numbers, multiply all ratios by a small integer to obtain whole numbers.

Example Scenario:

A compound is composed of 40.0% carbon, 6.7% hydrogen, and 53.3% oxygen by mass. What is its empirical formula?

1. Assume 100 g sample: 40.0 g C, 6.7 g H, 53.3 g O
2. Convert to moles:
 1. C: $40.0 \text{ g} / 12.01 \text{ g/mol} = 3.33 \text{ mol}$
 2. H: $6.7 \text{ g} / 1.01 \text{ g/mol} = 6.63 \text{ mol}$
 3. O: $53.3 \text{ g} / 16.00 \text{ g/mol} = 3.33 \text{ mol}$
3. Divide by the smallest molar quantity (3.33 mol):
 1. C: $3.33 / 3.33 = 1$
 2. H: $6.63 / 3.33 \approx 2$
 3. O: $3.33 / 3.33 = 1$

The empirical formula is CH_2O .

Step 2: Calculate the Empirical Formula Weight

Once the empirical formula is determined, calculate its molecular weight by summing the atomic weights of all atoms in the empirical formula. For CH_2O , the empirical formula weight is $(1 \times 12.01 \text{ g/mol}) + (2 \times 1.01 \text{ g/mol}) + (1 \times 16.00 \text{ g/mol}) = 30.03 \text{ g/mol}$.

Step 3: Determine the Multiple 'n'

You'll be given the molecular weight of the compound. Divide the molecular weight by the empirical formula weight calculated in Step 2 to find the integer 'n'.

Example Scenario (Continuing):

The molecular weight of the compound is 180.18 g/mol.

$$1. \quad n = 180.18 \text{ g/mol} / 30.03 \text{ g/mol} \approx 6$$

Step 4: Determine the Molecular Formula

Multiply each subscript in the empirical formula by the integer 'n' found in Step 3.

Example Scenario (Concluding):

Empirical formula = CH_2O , $n = 6$

$$1. \quad \text{Molecular formula} = (\text{CH}_2\text{O})_6 = \text{C}_6\text{H}_{12}\text{O}_6$$

This is the molecular formula for glucose.

4. Empirical Formula: CH_4

Step 2: Empirical Formula Weight

1. $CH_4: (1 \times 12.01 \text{ g/mol}) + (4 \times 1.01 \text{ g/mol}) = 16.05 \text{ g/mol}$

Step 3: Determine 'n'

1. $n = \text{Molecular Weight} / \text{Empirical Formula Weight} = 16.0 \text{ g/mol} / 16.05 \text{ g/mol} \approx 1$

Step 4: Molecular Formula

1. $(CH_4)_1 = CH_4$

Answer: CH_4 (Methane)

Question 2:

Given: 26.6% K, 35.4% Cr, 38.0% O; Molecular Weight = 394.3 g/mol

Step 1: Empirical Formula from Percentage Composition

1. Assume 100 g: 26.6 g K, 35.4 g Cr, 38.0 g O
2. Moles:
 1. K: $26.6 \text{ g} / 39.10 \text{ g/mol} = 0.680 \text{ mol}$
 2. Cr: $35.4 \text{ g} / 52.00 \text{ g/mol} = 0.681 \text{ mol}$
 3. O: $38.0 \text{ g} / 16.00 \text{ g/mol} = 2.375 \text{ mol}$
3. Divide by smallest (0.680 mol):
 1. K: $0.680 / 0.680 = 1$
 2. Cr: $0.681 / 0.680 \approx 1$
 3. O: $2.375 / 0.680 \approx 3.49 \approx 3.5$. Multiply by 2 to get whole numbers:
K: 2, Cr: 2, O: 7
4. Empirical Formula: $K_2Cr_2O_7$

Step 2: Empirical Formula Weight

1. $\text{K}_2\text{Cr}_2\text{O}_7$: $(2 \times 39.10 \text{ g/mol}) + (2 \times 52.00 \text{ g/mol}) + (7 \times 16.00 \text{ g/mol}) = 78.20 + 104.00 + 112.00 = 294.20 \text{ g/mol}$

Step 3: Determine 'n'

1. $n = \text{Molecular Weight} / \text{Empirical Formula Weight} = 394.3 \text{ g/mol} / 294.20 \text{ g/mol} \approx 1.34$. *Correction: There might be a slight rounding issue or the provided molecular weight is approximate. Let's re-evaluate the ratios for a potentially cleaner result, or assume the molecular weight is exact for the given empirical formula weight calculation. If we stick to the empirical formula weight of 294.20, and assume the molecular weight is correct, the ratio is not a clean integer. Let's assume the molecular weight is a typo and recalculate based on a likely integer multiple.* If we assume the molecular weight should be around 294.20, then $n=1$. However, if the molecular weight is indeed 394.3, there might be a different empirical formula or error in the problem statement. *For the purpose of this educational worksheet, let's proceed assuming a slight imprecision in the provided MW for $\text{K}_2\text{Cr}_2\text{O}_7$, aiming for an integer multiplier. A common compound with this elemental composition is potassium dichromate ($\text{K}_2\text{Cr}_2\text{O}_7$). Its MW is indeed around 294.20 g/mol.* Let's assume the provided molecular weight of 394.3 is incorrect for this elemental composition. If we were to hypothesize a different common chromium compound, it's difficult without more context. * Let's *assume* there was a typo in the question and the molecular weight was meant to result in a simple integer. If $n=1$, then the molecular formula is $\text{K}_2\text{Cr}_2\text{O}_7$. Let's check common compounds. *Revisiting the steps to ensure no miscalculation:* Moles K: 0.680, Moles Cr: 0.681, Moles O: 2.375. Ratio K:Cr:O = 1:1:3.5. Multiply by 2: $\text{K}_2\text{Cr}_2\text{O}_7$. EF Wt = 294.20 g/mol. If the molecular weight is 394.3 g/mol, then $n = 394.3 / 294.20 = 1.34$.

This is not a whole number. *Let's re-examine the percentage composition for common compounds.* Potassium dichromate ($K_2Cr_2O_7$): $K (2 \times 39.10) / (2 \times 39.10 + 2 \times 52.00 + 7 \times 16.00) = 78.20 / 294.20 = 26.6\%$. $Cr (2 \times 52.00) / 294.20 = 104 / 294.20 = 35.35\%$. $O (7 \times 16.00) / 294.20 = 112 / 294.20 = 38.07\%$. The percentage composition matches potassium dichromate very well. It is highly probable that the provided molecular weight (394.3 g/mol) is an error in the question, and the intended molecular weight should be close to 294.20 g/mol, making $n=1$. **Assuming the molecular weight should be approximately 294.2 g/mol for $K_2Cr_2O_7$:** $n = 294.2 \text{ g/mol} / 294.2 \text{ g/mol} = 1$

Step 4: Molecular Formula

$$1. (K_2Cr_2O_7)_1 = K_2Cr_2O_7$$

Answer: $K_2Cr_2O_7$ (Potassium Dichromate)

Note: This question highlights the importance of cross-referencing with known compounds and being aware of potential errors in problem statements.

Question 3:

Given: 0.750 g sample burned, produced 1.65 g CO_2 and 0.676 g H_2O ;
Molecular Weight = 90.0 g/mol

Step 1: Determine grams of C and H from combustion products

1. Grams of C in CO_2 : $(12.01 \text{ g C} / 44.01 \text{ g } CO_2) \times 1.65 \text{ g } CO_2 = 0.450 \text{ g C}$
2. Grams of H in H_2O : $(2 \times 1.01 \text{ g H} / 18.02 \text{ g } H_2O) \times 0.676 \text{ g } H_2O = 0.0757 \text{ g H}$

Step 2: Check for Oxygen (by difference)

1. Total mass of sample = 0.750 g
2. Mass of C + Mass of H = 0.450 g + 0.0757 g = 0.5257 g
3. Mass of O = Total sample mass - (Mass of C + Mass of H) = 0.750 g - 0.5257 g = 0.2243 g O

Step 3: Convert masses to moles

1. C: $0.450 \text{ g} / 12.01 \text{ g/mol} = 0.0375 \text{ mol}$
2. H: $0.0757 \text{ g} / 1.01 \text{ g/mol} = 0.0750 \text{ mol}$
3. O: $0.2243 \text{ g} / 16.00 \text{ g/mol} = 0.0140 \text{ mol}$

Step 4: Determine Empirical Formula

1. Divide by smallest (0.0140 mol):
 1. C: $0.0375 / 0.0140 \approx 2.68 \approx 2.5$. Multiply by 2: 5
 2. H: $0.0750 / 0.0140 \approx 5.36 \approx 5.5$. Multiply by 2: 11
 3. O: $0.0140 / 0.0140 = 1$. Multiply by 2: 2
2. Empirical Formula: $\text{C}_5\text{H}_{11}\text{O}_2$

Step 5: Empirical Formula Weight

1. $\text{C}_5\text{H}_{11}\text{O}_2$: $(5 \times 12.01 \text{ g/mol}) + (11 \times 1.01 \text{ g/mol}) + (2 \times 16.00 \text{ g/mol}) = 60.05 + 11.11 + 32.00 = 103.16 \text{ g/mol}$

Step 6: Determine 'n'

1. $n = \text{Molecular Weight} / \text{Empirical Formula Weight} = 90.0 \text{ g/mol} / 103.16 \text{ g/mol} \approx 0.87$. *Error detected. The resulting empirical formula weight (103.16) is higher than the given molecular weight (90.0). This indicates an error in the calculation or the problem statement.* Let's re-check the combustion calculation. Grams of C: 0.450 g. Moles C: 0.0375 mol. Grams of H: 0.0757 g. Moles H: 0.0750 mol. Mass of C+H = 0.5257 g. Sample mass = 0.750 g. Mass of O = 0.750 - 0.5257 = 0.2243 g. Moles O = 0.0140 mol. Ratios: C: $0.0375/0.0140 = 2.68$ H:

$0.0750/0.0140 = 5.36$ O: $0.0140/0.0140 = 1$ Multiplying by 2: C: 5.36
 $\rightarrow 5$, H: 10.72 $\rightarrow 11$, O: 2. This gives $C_5H_{11}O_2$ with a weight of 103.16 g/mol. *Let's assume the molecular weight is correct and try to find an empirical formula that fits. This suggests a potential recalculation of moles or a very precise ratio is needed.* Let's try dividing by a different value or check for alternative ratios. If we assume the molecular formula is $C_4H_{10}O$, MW = $(4 \times 12.01) + (10 \times 1.01) + 16.00 = 48.04 + 10.10 + 16.00 = 74.14$. Not 90. If we assume $C_5H_{10}O$, MW = $(5 \times 12.01) + (10 \times 1.01) + 16.00 = 60.05 + 10.10 + 16.00 = 86.15$. Closer. If we assume $C_5H_{12}O$, MW = $(5 \times 12.01) + (12 \times 1.01) + 16.00 = 60.05 + 12.12 + 16.00 = 88.17$. Closer. Let's re-examine the mole ratios for a simpler formula that might lead to a MW of 90. Consider the elemental composition from combustion: C=0.450g, H=0.0757g, O=0.2243g. Percentage composition: C: $(0.450 / 0.750) \times 100 = 60.0\%$ H: $(0.0757 / 0.750) \times 100 = 10.1\%$ O: $(0.2243 / 0.750) \times 100 = 29.9\%$ Let's find the empirical formula from these percentages: Assume 100g: 60.0g C, 10.1g H, 29.9g O Moles: C: $60.0 / 12.01 = 5.00$ mol H: $10.1 / 1.01 = 10.0$ mol O: $29.9 / 16.00 = 1.87$ mol Divide by smallest (1.87 mol): C: $5.00 / 1.87 \approx 2.67 \approx 2.5$. Multiply by 2: 5 H: $10.0 / 1.87 \approx 5.35 \approx 5.5$. Multiply by 2: 11 O: $1.87 / 1.87 = 1$. Multiply by 2: 2 Empirical Formula: $C_5H_{11}O_2$. Empirical Formula Weight = 103.16 g/mol. This still leads to an EF Wt > MW. This strongly indicates an issue with the question's provided values. *Let's consider a different common compound with a MW around 90, and see if the combustion data is close. Propanoic acid ($C_3H_6O_2$) has MW = $(3 \times 12.01) + (6 \times 1.01) + (2 \times 16.00) = 36.03 + 6.06 + 32.00 = 74.09$. Not 90. Butyric acid ($C_4H_8O_2$) has MW = $(4 \times 12.01) + (8 \times 1.01) + (2 \times 16.00) = 48.04 + 8.08 + 32.00 = 88.12$. This is very close to 90.0 g/mol.* Let's assume the molecular formula is $C_4H_8O_2$ and check if the combustion data is consistent. If MW = 90.0 g/mol, and EF is $C_4H_8O_2$ (MW 88.12), then n would be $90.0/88.12 = 1.02$. This is close to 1. So, it's likely the molecular formula is indeed

$C_4H_8O_2$. Let's recalculate the empirical formula derived from the combustion data assuming a slight error in measurement to fit $C_4H_8O_2$. Let's re-evaluate the mole ratios, aiming for C:4, H:8, O:2. Moles C: 0.0375, Moles H: 0.0750, Moles O: 0.0140. Ratio C:H:O = 0.0375 : 0.0750 : 0.0140 If we divide by 0.0140: 2.68 : 5.36 : 1. This is not $C_4H_8O_2$. *There appears to be a significant inconsistency in the provided data for Question 3. The combustion analysis leads to an empirical formula whose weight exceeds the given molecular weight. This often happens if there are errors in the experimental data or the provided values.* **Let's assume a hypothetical scenario where the empirical formula weight was 45.0 g/mol and the molecular weight was 90.0 g/mol. Then $n=2$. If the empirical formula was, for example, CH_2O , then the molecular formula would be $C_2H_4O_2$ (acetic acid).** **Given the difficulty in reconciling the numbers, let's try a different approach. If the molecular formula is $C_4H_8O_2$ (MW $\approx$ 90), let's calculate the expected combustion products from a 0.750g sample.** Mass percentage of elements in $C_4H_8O_2$: C: $(4 \times 12.01) / 88.12 \times 100 = 54.5\%$ H: $(8 \times 1.01) / 88.12 \times 100 = 9.18\%$ O: $(2 \times 16.00) / 88.12 \times 100 = 36.3\%$ From 0.750g sample: C: $0.750 \text{ g} \times 0.545 = 0.409 \text{ g C} \rightarrow 0.409 / 12.01 = 0.0341 \text{ mol C}$ H: $0.750 \text{ g} \times 0.0918 = 0.0689 \text{ g H} \rightarrow 0.0689 / 1.01 = 0.0682 \text{ mol H}$ O: $0.750 \text{ g} \times 0.363 = 0.272 \text{ g O} \rightarrow 0.272 / 16.00 = 0.0170 \text{ mol O}$ Convert to grams of CO_2 and H_2O : CO_2 : $0.0341 \text{ mol C} \times (44.01 \text{ g } CO_2 / 1 \text{ mol C}) = 1.50 \text{ g } CO_2$. H_2O : $0.0682 \text{ mol H} \times (18.02 \text{ g } H_2O / 2 \text{ mol H}) = 0.614 \text{ g } H_2O$. These calculated values (1.50 g CO_2 , 0.614 g H_2O) are quite different from the provided ones (1.65 g CO_2 , 0.676 g H_2O). This further confirms a problem with the question's data. **For educational purposes, let's assume the empirical formula derived from the initial combustion analysis was correct, even though the MW doesn't fit cleanly. If we *had* to proceed with the initial derivation:** Empirical Formula: $C_5H_{11}O_2$ (EF Wt = 103.16 g/mol). If MW = 90.0 g/mol, and EF Wt = 103.16 g/mol, it's impossible

to have a molecular formula. **Conclusion for Question 3: The provided data is inconsistent. However, if forced to choose based on common organic molecules with MW around 90, $C_4H_8O_2$ is the most likely candidate (e.g., Butyric acid or esters). But the combustion data does not support this directly with the given values. For a worksheet, it's best to have consistent data. If we ignore the combustion and focus on the MW: if EF is CH_2O , then $C_6H_{12}O_6$ (MW ~180). If EF is CH , MW for CH is 13, so C_7H_7 would be ~91. The combustion data is the key, and it's flawed here. Let's assume a typo and the molecular weight was intended to be ~103.16, in which case the molecular formula would be $C_5H_{11}O_2$.** **Answer (with disclaimer):** Due to inconsistencies in the provided data, a definitive answer cannot be reached without making assumptions or correcting the problem statement. If we assume a correct empirical formula calculation based on the combustion data leading to an EF Wt of 103.16 g/mol, and *if* the molecular weight were meant to be approximately 103.16 g/mol, then the molecular formula would be $C_5H_{11}O_2$. The given MW of 90.0 g/mol makes this problem unsolvable as stated.

Question 4:

Given: Empirical Formula = NO_2 ; Molecular Weight = 92.0 g/mol

Step 1: Empirical Formula Weight

$$1. \text{ NO}_2: (1 \times 14.01 \text{ g/mol}) + (2 \times 16.00 \text{ g/mol}) = 14.01 + 32.00 = 46.01 \text{ g/mol}$$

Step 2: Determine 'n'

$$1. n = \text{Molecular Weight} / \text{Empirical Formula Weight} = 92.0 \text{ g/mol} / 46.01 \text{ g/mol} \approx 2$$

Step 3: Molecular Formula

1. $(\text{NO}_2)_2 = \text{N}_2\text{O}_4$

Answer: N_2O_4 (Dinitrogen Tetroxide)

Question 5:

Given: 47.0% N, 53.0% P; Molecular Weight = 280.1 g/mol

Step 1: Empirical Formula from Percentage Composition

1. Assume 100 g: 47.0 g N, 53.0 g P
2. Moles:
 1. N: $47.0 \text{ g} / 14.01 \text{ g/mol} = 3.35 \text{ mol}$
 2. P: $53.0 \text{ g} / 30.97 \text{ g/mol} = 1.71 \text{ mol}$
3. Divide by smallest (1.71 mol):
 1. N: $3.35 / 1.71 \approx 1.96 \approx 2$
 2. P: $1.71 / 1.71 = 1$
4. Empirical Formula: P N_2 (or NP_2 - careful with order, usually element with lower electronegativity first, or alphabetical) - Let's stick to NP_2 as derived. Wait, P is less electronegative, so NP_2 is correct. Or N_2P . Let's confirm standard naming. Phosphorus nitride nomenclature can vary. For empirical formulas, the ratio derived is key. Let's write it as N_2P .

Step 2: Empirical Formula Weight

1. $\text{N}_2\text{P}: (2 \times 14.01 \text{ g/mol}) + (1 \times 30.97 \text{ g/mol}) = 28.02 + 30.97 = 58.99 \text{ g/mol}$

Step 3: Determine 'n'

1. $n = \text{Molecular Weight} / \text{Empirical Formula Weight} = 280.1 \text{ g/mol} / 58.99 \text{ g/mol} \approx 4.75$. *Again, not a clean integer. Let's re-evaluate

the mole ratios. * Moles N: 3.35, Moles P: 1.71. Ratio N:P = 3.35 : 1.71. Divide by 1.71: N: 1.96, P: 1. This is very close to N:2, P:1. So, N_2P . EF Wt = 58.99. If $n = 280.1 / 58.99 = 4.75$. This suggests there might be an error in the percentage composition or the molecular weight. Let's reconsider the possibility of N_4P_2 if we multiplied by 2? No, that would be $n=2$. EF = N_2P , MW = 280.1. If $n=4$: $(N_2P)_4 = N_8P_4$. MW = $4 * 58.99 = 235.96$. Too low. If $n=5$: $(N_2P)_5 = N_{10}P_5$. MW = $5 * 58.99 = 294.95$. This is closer to 280.1. Let's check the percentages for $N_{10}P_5$. This is equivalent to N_2P . So, the empirical formula N_2P and its weight (58.99 g/mol) are correct based on the percentages. The issue is the molecular weight. If $n=5$, the MW would be around 294.95 g/mol. If the MW is 280.1, then $n = 280.1 / 58.99 = 4.75$. *Let's assume there's a slight rounding difference and n is meant to be 5. * If $n = 5$, then Molecular Formula = $(N_2P)_5 = N_{10}P_5$. Let's re-examine the percentages if the molecular formula were $N_{10}P_5$. This is a 5-fold multiple of N_2P . Percentage of N in $N_2P = (2 * 14.01) / 58.99 = 28.02 / 58.99 = 47.50\%$. Percentage of P in $N_2P = (1 * 30.97) / 58.99 = 30.97 / 58.99 = 52.50\%$. These percentages (47.50% N, 52.50% P) are very close to the given ones (47.0% N, 53.0% P). The molecular weight for $N_{10}P_5$ is $5 * 58.99 = 294.95$ g/mol. The provided molecular weight is 280.1 g/mol. The difference is significant (280.1 vs 294.95). *Given the discrepancy, it's possible the intended compound is something else, or there's a data error. However, based on the close percentage match and a near-integer multiplier, $N_{10}P_5$ is the most plausible molecular formula if we round 'n' to 5. *

Answer (with disclaimer): Due to a discrepancy between the calculated molecular weight for $N_{10}P_5$ (294.95 g/mol) and the provided molecular weight (280.1 g/mol), this problem has inconsistencies. However, based on the percentage composition and a calculated 'n' close to 5, the most likely molecular formula,

assuming the percentage composition is accurate and the molecular weight has a slight error, is $N_{10}P_5$. If the molecular weight were exactly 294.95, then $n=5$ and the formula would be $N_{10}P_5$.

Questions & Answers About molecular formula worksheet with answers

No	Question	Answer
----	----------	--------

1	What exactly IS a molecular formula worksheet, and why should I care about it?	A molecular formula worksheet helps you practice identifying the actual number and type of atoms in a molecule. It's crucial for understanding a compound's composition, properties, and how it reacts.
2	How do I start solving a molecular formula worksheet if I'm a beginner?	Begin by mastering empirical formulas. Then, use the molar mass of the compound to determine the multiplier needed to convert the empirical formula to the molecular formula.
3	What's the difference between an empirical formula and a molecular formula, and how does a worksheet highlight this?	The empirical formula is the simplest whole-number ratio of atoms, while the molecular formula shows the actual number of atoms. Worksheets often provide the empirical formula and molar mass, requiring you to find the molecular formula.
4	I keep getting confused when calculating molar mass for the worksheet. Any tips?	Keep a periodic table handy! Accurately summing the atomic masses of each element in the formula, multiplied by the number of atoms of that element, is key.
5	Are there common pitfalls to watch out for on molecular formula worksheets?	Yes! Double-check your calculations for molar mass, ensure you're using the correct atomic masses, and always simplify your empirical formula before proceeding.
6	How can I check my answers on a molecular formula worksheet effectively?	If possible, use an answer key. Otherwise, reverse the process: start with your calculated molecular formula, find its empirical formula, and verify the molar mass.
7	My worksheet involves compounds with polyatomic ions. What's the best way to handle those?	Treat the polyatomic ion as a single unit when calculating molar mass, but remember to account for the number of times that ion appears in the overall molecular formula.

8	Where can I find more molecular formula worksheets online to practice?	Many educational websites, chemistry blogs, and online learning platforms offer free molecular formula worksheets with solutions. Searching for 'molecular formula practice problems' will yield many results.
