Understanding Probability: A

Foundation

Probability deals with the likelihood of events occurring. It quantifies uncertainty using values between 0 and 1, where 0 represents impossibility and 1 represents certainty. Fundamental concepts include:

- Sample Space: **The set of all possible outcomes.**
- Event:

A subset of the sample space.

- Probability of an Event: **The likelihood of the event occurring, often calculated as the ratio of favorable outcomes to the total possible outcomes.**

Example: **Rolling a six-sided die. The sample space is {1, 2, 3, 4, 5, 6}. The probability of rolling a 3 is 1/6.**

Conditional Probability and Bayes' Theorem

Conditional probability calculates the probability of an event occurring given that another event has already occurred. Bayes' Theorem allows us to update probabilities in light of new evidence.

Example: *If a coin is flipped and lands heads, what is the probability that the next flip will also be heads? (Assuming the coin is fair, the answer is 0.5). Bayes' Theorem is used in spam filtering, medical diagnosis, and other applications.*

Stochastic Processes: Beyond Single Events

Stochastic processes describe how systems evolve over time based on random factors. Key types include:

- Markov Chains: *Processes where the future depends only on the present state, not the past.*
- Poisson Processes: *Count the number of events occurring in a given time interval.*
- Wiener Processes (Brownian Motion): **Model random fluctuations in continuous time.**

Illustrative Chart:

Comparing Different Stochastic Processes | Process Type | Key Characteristic | Example | ||| | Markov Chain | Future depends only on present | Stock price movement (simplified model) | | Poisson Process | Counts events in time | Number of customers arriving at a store | | Wiener Process | Continuous random fluctuations | Stock price movements (more realistic model) |

Solving Probability and Stochastic Processes Quiz Questions

- Basic Probability: Determine the probability of different events from a defined sample space.
- Conditional Probability: **Calculating the probability of an event based on prior knowledge.**
- Markov Chains: **Identifying state transitions and calculating probabilities of reaching certain states.**

Unlocking the Mysteries: Probability and Stochastic Processes Quiz Solutions Demystified

Feeling a little overwhelmed by that recent probability and stochastic processes quiz? You're not alone! These subjects, while foundational to many scientific and engineering fields, can be a real head-scratcher. From understanding the likelihood of events to modeling systems that evolve randomly over time, the concepts can get intricate. But here's the good news: with a solid grasp of the fundamentals and a systematic approach to problem-solving, those complex questions become much more manageable. This article is designed to be your ultimate companion to navigating and understanding common probability and stochastic processes quiz solutions. We'll break down key concepts, tackle typical problem types, and offer insights into how to approach them effectively.

Why Are Probability and Stochastic Processes So Important?

Before we dive into quiz solutions, let's quickly remind ourselves why these topics are so crucial. Probability theory provides the mathematical framework for quantifying uncertainty. It helps us

understand the likelihood of various outcomes in random experiments, from a coin flip to the stock market. Stochastic processes, on the other hand, extend these ideas to systems that change over time in a random manner. Think about the movement of particles in a gas (Brownian motion), the spread of a disease, or the fluctuations of an investment portfolio. Understanding these dynamic systems is vital for prediction, analysis, and decision-making in a world that's anything but deterministic.

Common Probability Concepts You'll Encounter in Quizzes

Most probability quizzes will test your understanding of core principles. Let's revisit some of these and see how they might appear in a quiz context.

1. Basic Probability and Events

At its heart, probability is about the ratio of favorable outcomes to the total possible outcomes. When you see a question asking for the "probability of event A," you're usually looking at something like $P(A) = (\text{Number of ways A can occur}) / (\text{Total number of possible outcomes})$. * **Key Terms:** Sample space, event, mutually exclusive events, independent events, complementary events. * **Typical Quiz Question:** "What is the probability of rolling a sum of 7 with two fair six-sided dice?" * **Solution Approach:** Identify the sample space (36 possible outcomes). List the combinations that sum to 7: (1,6), (2,5), (3,4), (4,3), (5,2), (6,1). There are 6 favorable outcomes. So, $P(\text{sum}=7) = 6/36 = 1/6$.

2. Conditional Probability and Bayes' Theorem

Conditional probability is about the likelihood of an event occurring given that another event has already occurred. This is often

denoted as $P(A|B)$ – the probability of A given B. Bayes' Theorem is a powerful tool for updating probabilities based on new evidence. *

Key Terms: Conditional probability, joint probability, Bayes' Theorem. *

Typical Quiz Question: "A medical test for a rare disease has a 99% accuracy rate for detecting the disease (true positive) and a 95% accuracy rate for correctly identifying those who do not have the disease (true negative). If 1% of the population has the disease, what is the probability that a person who tests positive actually has the disease?" *

Solution Approach: This is a classic Bayes' Theorem problem. Let D be the event of having the disease, and T be the event of testing positive. *

$P(D) = 0.01$ (prevalence of the disease) *

$P(\text{not } D) = 0.99$ *

$P(T|D) = 0.99$ (true positive rate) *

$P(T|\text{not } D) = 0.05$ (false positive rate, since true negative is 0.95) *

We want to find $P(D|T)$. *

Bayes' Theorem: $P(D|T) = [P(T|D) * P(D)] / P(T)$ *

We need to calculate $P(T)$, the overall probability of testing positive, which can happen in two ways: a true positive or a false positive. *

$P(T) = P(T|D) * P(D) + P(T|\text{not } D) * P(\text{not } D)$ *

$P(T) = (0.99 * 0.01) + (0.05 * 0.99) = 0.0099 + 0.0495 = 0.0594$ *

Now, $P(D|T) = (0.99 * 0.01) / 0.0594 = 0.0099 / 0.0594 \approx 0.1667$ or 16.67%. *

Insight: Even with a highly accurate test, the low prevalence of the disease means a positive result doesn't guarantee infection. This highlights the importance of prior probabilities.

3. Random Variables and Probability Distributions

A random variable assigns a numerical value to the outcome of a random phenomenon. Understanding different probability distributions (like binomial, Poisson, normal, exponential) is key to modeling various real-world scenarios. *

Key Terms: Discrete random variable, continuous random variable, probability mass function (PMF), probability density function (PDF), cumulative distribution function (CDF), expected value (mean), variance. *

Typical Quiz Question (Binomial): "A factory produces light bulbs

with a 2% defect rate. If 100 bulbs are randomly selected, what is the probability that exactly 3 are defective?" * **Solution

Approach:** This fits a binomial distribution since we have a fixed number of trials ($n=100$), each trial has two outcomes (defective or not), the probability of success (defect) is constant ($p=0.02$), and the trials are independent. The binomial probability formula is

$P(X=k) = C(n, k) * p^k * (1-p)^{(n-k)}$. * $n = 100$, $k = 3$, $p = 0.02$ *
 $P(X=3) = C(100, 3) * (0.02)^3 * (0.98)^{(100-3)}$ * $C(100, 3) = 100! / (3! * 97!) = (100 * 99 * 98) / (3 * 2 * 1) = 161700$ * $P(X=3) =$
 $161700 * (0.000008) * (0.98)^{97}$ * Calculating $(0.98)^{97}$ requires a

calculator or statistical software. The result will be approximately 0.1396. * **Insight:** For a large number of trials and a small

probability of success, the Poisson distribution can sometimes be used as an approximation to the binomial distribution, especially if np is not too large. * **Typical Quiz Question (Poisson):** "On

average, 5 customers arrive at a shop per hour. What is the probability that exactly 2 customers arrive in a given hour?" *

Solution Approach: This scenario follows a Poisson distribution, which models the number of events occurring in a fixed interval of time or space, given a constant average rate. The Poisson probability formula is $P(X=k) = (\lambda^k * e^{(-\lambda)}) / k!$ * λ (lambda, the average rate) = 5 customers/hour * k (number of events) = 2 *
 $P(X=2) = (5^2 * e^{(-5)}) / 2! = (25 * e^{(-5)}) / 2 * e^{(-5)} \approx 0.006738$

* $P(X=2) \approx (25 * 0.006738) / 2 \approx 0.0842$ * **Insight:** The Poisson distribution is incredibly useful for modeling events like calls to a

call center, website visits, or radioactive decay. * **Typical Quiz Question (Normal):** "The heights of adult males in a certain

population are normally distributed with a mean of 175 cm and a standard deviation of 7 cm. What is the probability that a randomly selected adult male is taller than 185 cm?" * **Solution Approach:** For a normal distribution, we use Z-scores to find probabilities. The

Z-score formula is $Z = (X - \mu) / \sigma$, where X is the value, μ is the mean, and σ is the standard deviation. * $X = 185$ cm, $\mu = 175$ cm, σ

$= 7 \text{ cm} * Z = (185 - 175) / 7 = 10 / 7 \approx 1.43$ * We need to find $P(Z > 1.43)$. This is usually found using a standard normal distribution table (Z-table) or statistical software. The table typically gives $P(Z < z)$. So, $P(Z > 1.43) = 1 - P(Z < 1.43)$. * Looking up $Z=1.43$ in a Z-table, $P(Z < 1.43)$ is approximately 0.9236. * Therefore, $P(X > 185) = P(Z > 1.43) = 1 - 0.9236 = 0.0764$ or 7.64%. * **Insight:** The normal distribution is ubiquitous in nature and statistics, often appearing when summing up many small, independent random effects. Understanding how to work with Z-scores and CDFs is crucial.

4. Expected Value and Variance

The expected value ($E[X]$) of a random variable represents its average value over many trials. Variance ($\text{Var}(X)$) measures how spread out the distribution is. * **Key Concepts:** $E[X] = \sum [x * P(X=x)]$ for discrete, $E[X] = \int [x * f(x)] dx$ for continuous. $\text{Var}(X) = E[(X - E[X])^2] = E[X^2] - (E[X])^2$. * **Typical Quiz Question:** "Consider a game where you win \$10 with probability 0.3, \$5 with probability 0.5, and lose \$20 with probability 0.2. What is the expected winnings?" * **Solution Approach:** $E[\text{Winnings}] = (10 * 0.3) + (5 * 0.5) + (-20 * 0.2) = 3 + 2.5 - 4 = 1.5$ * The expected winnings are \$1.50. * **Navigation:** Stochastic processes introduce the element of time or another index. They are used to model systems that evolve randomly.

1. Markov Chains

Markov chains are a fundamental type of stochastic process where the future state depends only on the current state, not on the sequence of events that preceded it (the "Markov property"). * **Key Terms:** States, transition probabilities, transition matrix, stationary distribution. * **Typical Quiz Question:** "Consider a

simple weather model: if it's sunny today, there's an 80% chance it's sunny tomorrow and a 20% chance it's rainy. If it's rainy today, there's a 60% chance it's sunny tomorrow and a 40% chance it's rainy. If today is sunny, what is the probability it will be sunny in two days?"

Solution Approach: This involves a transition matrix. Let state 1 be sunny (S) and state 2 be rainy (R).

Transition Matrix $P = \begin{bmatrix} 0.8 & 0.2 \\ 0.6 & 0.4 \end{bmatrix}$ (Row i , Column j is $P(\text{state } j \mid \text{state } i)$)

Initial state vector $V_0 = [1, 0]$ (since today is sunny)

To find the state probabilities after one day: $V_1 = V_0 * P = [1, 0] * \begin{bmatrix} 0.8 & 0.2 \\ 0.6 & 0.4 \end{bmatrix} = [0.8, 0.2]$. This means there's an 80% chance of sun and 20% chance of rain tomorrow.

To find the state probabilities after two days: $V_2 = V_1 * P = [0.8, 0.2] * \begin{bmatrix} 0.8 & 0.2 \\ 0.6 & 0.4 \end{bmatrix}$

$$V_2 = [(0.8*0.8 + 0.2*0.6), (0.8*0.2 + 0.2*0.4)]$$

$$V_2 = [0.64 + 0.12, 0.16 + 0.08] = [0.76, 0.24]$$

So, the probability of it being sunny in two days is 0.76 or 76%.

Insight: Markov chains are used in areas like natural language processing (predicting the next word), search engine algorithms (PageRank), and reliability engineering.

2. Poisson Processes

A Poisson process models the occurrence of events randomly over time, where the average rate of occurrence is constant. The number of events in disjoint time intervals are independent.

Key Terms: Arrival rate (λ), inter-arrival times, memoryless property.

Typical Quiz Question: "Customers arrive at a bank according to a Poisson process with a rate of 10 customers per hour. What is the probability that the next customer arrives within the next 15 minutes?"

Solution Approach: The number of arrivals in a time interval of length t follows a Poisson distribution with rate λt .

$\lambda = 10$ customers/hour. $t = 15$ minutes = 0.25 hours.

The rate for the 15-minute interval is $\lambda t = 10 * 0.25 = 2.5$.

The time between arrivals (inter-arrival time) in a Poisson process follows an exponential distribution with parameter λ . The PDF is $f(t) = \lambda e^{(-\lambda t)}$.

* We want the probability that the next arrival is *within* 0.25 hours. This is equivalent to asking for the probability that the inter-arrival time is less than or equal to 0.25 hours. * For an exponential distribution, $P(T \leq t) = 1 - e^{(-\lambda t)}$. * $P(T \leq 0.25) = 1 - e^{(-10 * 0.25)} = 1 - e^{(-2.5)} * e^{(-2.5)} \approx 0.0821$ * $P(T \leq 0.25) \approx 1 - 0.0821 = 0.9179$ or 91.79%. * **Insight:** The memoryless property of the exponential distribution is key here – the time until the next event is independent of how long we've already waited.

3. Brownian Motion (Wiener Process) **Brownian motion is a continuous-time stochastic process that describes the random movement of particles suspended in a fluid. It's a fundamental building block for many advanced models in finance and physics.** * **Key Terms:** Increments, variance, continuity, quadratic variation. * **Typical Quiz Question (Conceptual):** "What are the key properties of a standard Brownian motion process $W(t)$?" * **Solution Approach:** * $W(0) = 0$ (starts at zero). * **Independent increments:** For any $0 \leq t_1 < t_2 \leq t_3 < t_4$, the random variables $W(t_2) - W(t_1)$ and $W(t_4) - W(t_3)$ are independent. * **Stationary increments:** The distribution of $W(t+s) - W(s)$ depends only on t , not on s . * **Normal increments:** For any $t > 0$, $W(t) - W(s)$ is normally distributed with mean 0 and variance $t-s$. Specifically, $W(t) \sim N(0, t)$. * **Insight:** While direct calculation questions might be less common in introductory quizzes, understanding these properties is vital for grasping more complex applications like Black-Scholes models in financial mathematics.

Understanding the Landscape:

Core Concepts in Probability and Stochastic Processes

Before diving into specific quiz solutions, a solid grasp of foundational concepts is paramount. Probability theory deals with quantifying uncertainty, assigning numerical values to the likelihood of events occurring. Stochastic processes, on the other hand, are mathematical models that describe systems evolving randomly over time. They are the dynamic extension of probability, where randomness is a continuous or discrete factor influencing the system's state.

Key Probability Concepts

- 1. Events and Sample Spaces:** An event is an outcome or a set of outcomes of an experiment, while the sample space is the collection of all possible outcomes.
- 2. Probability Axioms:** These are the foundational rules governing probability assignments: non-negativity, certainty (probability of the sample space is 1), and additivity for mutually exclusive events.
- 3. Conditional Probability:** The probability of an event occurring given that another

event has already occurred. This is often represented as $P(A|B) = P(A \cap B) / P(B)$.

- 4. Independence: Two events are independent if the occurrence of one does not affect the probability of the other. For independent events A and B, $P(A \cap B) = P(A) * P(B)$.**
- 5. Random Variables: A variable whose value is a numerical outcome of a random phenomenon. They can be discrete (taking countable values) or continuous (taking any value within an interval).**
- 6. Probability Distributions: Functions that describe the**

likelihood of different outcomes for a random variable. Common examples include Bernoulli, Binomial, Poisson, Uniform, Exponential, and Normal distributions.

- 7. Expected Value and Variance:**
Expected value ($E[X]$)
represents the average outcome of a random variable, while variance ($\text{Var}[X]$) measures its spread or dispersion.

Key Stochastic Process Concepts

- 1. Markov Chains: Processes where the future state depends only on the current state, not on the sequence of events that**

preceded it. This "memoryless" property is a cornerstone.

- 2. Poisson Processes: Models for the number of events occurring in a fixed interval of time or space, assuming events are independent and occur at a constant average rate.**
- 3. Brownian Motion: A continuous-time stochastic process that models random walks, often used in finance to represent asset price movements.**
- 4. Martingales: Processes where the expected future value, given all past information, is equal to the current value.**
- 5. Stationarity: A property of a**

stochastic process where its statistical properties (like mean and variance) do not change over time.

Deconstructing Common Probability Quiz Problems and Their Solutions

Probability quizzes often test understanding of basic definitions, combinatorics, conditional probability, and the application of standard probability distributions. Let's explore some typical scenarios and how to approach their solutions.

Scenario 1: Combinatorics and Basic Probability

Problem Type: Calculating the probability of drawing specific cards from a deck, arranging items, or selecting a subset from a larger group.

Analytical Approach: These problems often require the use of combinations (nCr) and permutations (nPr). Remember, combinations are used when the order of selection doesn't matter, and permutations are used when the order is important. The basic probability formula is (Number of favorable outcomes) / (Total number of possible outcomes).

Example Solution Strategy: For drawing 2 red cards from a standard 52-card deck (26 red, 26 black):

- 1. Total ways to choose 2 cards from 52: $C(52, 2)$**
- 2. Ways to choose 2 red cards from 26: $C(26, 2)$**
- 3. Probability = $C(26, 2) / C(52, 2)$**

LSI Keywords: Combinations, Permutations, Sample space, Favorable outcomes, Deck of cards probability, Card drawing problems.

Scenario 2: Conditional Probability and Bayes' Theorem

Problem Type: Determining the

probability of an event given that another event has occurred, often involving medical testing or system reliability.

Analytical Approach: The formula $P(A|B) = P(A \cap B) / P(B)$ is central. Bayes' Theorem is crucial for updating probabilities as new evidence emerges: $P(A|B) = [P(B|A) * P(A)] / P(B)$.

Understanding the relationship between events and their complements is also key.

Example Solution Strategy: Consider a scenario with two tests for a disease. If the prevalence of the disease is low, but the test has a high false

positive rate, Bayes' Theorem is essential to calculate the true probability of having the disease given a positive test result.

LSI Keywords: Conditional probability, Bayes' Theorem applications, Updating probabilities, Medical test accuracy, False positive, False negative, Prior probability, Posterior probability.

Scenario 3: Probability Distributions

Problem Type: Calculating probabilities related to discrete events (e.g., number of defective items in a batch - Binomial or Poisson) or continuous

phenomena (e.g., arrival times, component lifetimes - Exponential or Normal).

Analytical Approach: Identify the underlying random variable and the appropriate probability distribution. For discrete distributions, this involves summing probabilities from a probability mass function (PMF). For continuous distributions, it involves integrating a probability density function (PDF) over a given range.

Example Solution Strategy: If a machine produces defective items with a probability of 0.05, and we want to find the probability of

having exactly 3 defective items in a sample of 10, we'd use the Binomial distribution:

- 1. $P(X=k) = C(n, k) * p^k * (1-p)^{(n-k)}$**
- 2. Here, $n=10$, $k=3$, $p=0.05$.**

For continuous problems, like the time until the next customer arrives at a store with an average arrival rate of 10 per hour, the Exponential distribution is often used.

LSI Keywords: Binomial distribution problems, Poisson distribution solutions, Exponential distribution calculations, Normal distribution

problems, Probability mass function (PMF), Probability density function (PDF), Expected value of a distribution, Variance of a distribution.

Tackling Stochastic Processes Quiz Questions

Stochastic process quizzes move beyond static probabilities to examine systems that evolve over time. These problems often involve analyzing sequences of random events and predicting future behavior.

Scenario 4: Markov Chains

Problem Type: Predicting the long-term behavior of a system

(e.g., market share of competing products, weather patterns) or calculating the probability of transitioning between states.

Analytical Approach: The core is the transition matrix, which defines the probabilities of moving from one state to another in a single time step. For stationary distributions, we solve for a probability vector that remains unchanged after a transition. For specific state probabilities at time 't', we multiply the initial state vector by the transition matrix raised to the power of 't'.

Example Solution Strategy: Given

a transition matrix for a simple weather model (Sunny, Cloudy, Rainy), we can calculate the probability of it being rainy on day 5, given it's sunny today, by raising the transition matrix to the power of 4 and multiplying it by the initial state vector $[1 \ 0 \ 0]$ (representing 100% sunny).

LSI Keywords: Markov chains explained, Transition matrix, Stationary distribution, State space, Time evolution of Markov chains, Absorbing Markov chains, First-step analysis.

Scenario 5: Poisson Processes

Problem Type: Modeling the

number of events in a fixed interval (e.g., customer arrivals, calls to a call center) or the time between events.

Analytical Approach: The Poisson distribution is used to find the probability of a certain number of events occurring given an average rate (λ). The time between events follows an Exponential distribution with the same rate parameter.

Example Solution Strategy: If calls arrive at a call center with an average rate of 5 per minute, the probability of receiving exactly 3 calls in a given minute can be calculated using the

Poisson PMF: $P(X=k) = (e^{-\lambda} * \lambda^k) / k!$, where $\lambda=5$ and $k=3$.

LSI Keywords: Poisson process modeling, Inter-arrival times, Rate parameter, Counting processes, Applications of Poisson distribution, Queueing theory basics.

Strategies for Effective Quiz Preparation and Solution Mastery

Simply memorizing formulas is rarely sufficient for truly understanding probability and stochastic processes. Effective preparation involves a multi-faceted approach:

1. Solidify Foundational Knowledge

Ensure a deep understanding of the axioms of probability, definitions of random variables, and the properties of different distributions. Revisit lecture notes, textbooks, and online resources regularly.

2. Practice, Practice, Practice

The key to mastering these subjects lies in solving a wide variety of problems. Work through textbook examples, homework assignments, and especially past quizzes or mock exams. Don't just get the answer; understand the reasoning behind it.

3. Understand the "Why" Behind the Formulas

For every formula, ask yourself: what does it represent? What are its assumptions? When is it applicable? This analytical mindset is crucial for tackling novel problems.

4. Visualize and Model

For stochastic processes, drawing state diagrams for Markov chains or visualizing the cumulative distribution function for continuous variables can greatly aid comprehension.

5. Identify Problem Patterns

As you practice, you'll begin to

recognize common problem archetypes. Learning to classify a problem quickly (e.g., "this is a conditional probability problem," or "this involves a Poisson process") can streamline your solution process.

6. Analyze Solutions Critically

When reviewing quiz solutions, don't just check if your answer was correct. Understand the steps taken by the solution provider. Were there alternative approaches? Could the solution be more efficient? This critical analysis hones your problem-solving skills.

7. Seek Clarification

If you consistently struggle with a particular concept or problem type, don't hesitate to ask your instructor or teaching assistant for help. Understanding your specific sticking points is vital.

Questions & Answers About probability and stochastic processes quiz solutions

No	Question	Answer
1	I'm stuck on a conditional probability problem involving a deck of cards. What's the general strategy for solving these types of quiz questions?	For conditional probability problems, especially with decks of cards, start by clearly defining the events involved. Use the formula $P(A B) = P(A \text{ and } B) / P(B)$. Often, it's helpful to list out all possible outcomes or draw a tree diagram to visualize the relationships between events and calculate the intersection and individual probabilities.
2	My quiz had a question about Markov chains, and I wasn't sure how to interpret the transition matrix. What's the key takeaway?	The transition matrix in a Markov chain represents the probabilities of moving from one state to another in a single step. Each row sums to 1, indicating that from any given state, there's a 100% chance of transitioning to some state (including staying in the same state). To predict future states, you multiply the current state vector by the transition matrix repeatedly.
3	I'm confused about the difference between stationary distribution and steady-state probabilities in stochastic processes. How do I distinguish them?	A stationary distribution is a probability distribution that remains unchanged over time, meaning the probabilities of being in each state are constant after many steps. Steady-state probabilities are the long-run probabilities of being in a particular state, which are often equal to the elements of the stationary distribution for ergodic Markov chains. The stationary distribution is a vector, while steady-state probabilities are individual values within that vector.

4	The quiz included a problem about Poisson processes. What's the most important concept to remember when solving these?	The core concept of a Poisson process is that events occur randomly and independently at a constant average rate. Key properties include that the number of events in disjoint time intervals are independent, and the number of events in an interval of length 't' follows a Poisson distribution with parameter ' λt ' (where ' λ ' is the rate).
5	I saw a question involving Bayesian inference and updating probabilities. What's the fundamental formula I should be looking for?	Bayesian inference uses Bayes' Theorem to update prior beliefs about an event based on new evidence. The fundamental formula is $P(A B) = [P(B A) * P(A)] / P(B)$, where $P(A)$ is the prior probability, $P(B A)$ is the likelihood, $P(B)$ is the marginal probability of the evidence, and $P(A B)$ is the posterior probability after observing the evidence.
