Probability and Statistics Solved Problems: A Comprehensive Guide

Probability and statistics are fundamental tools for understanding and interpreting data in various fields, from finance and engineering to social sciences and healthcare. This delves into the core concepts through solved problems, offering a practical and insightful exploration of these critical areas.

Understanding Probability

Probability measures the likelihood of an event occurring. It ranges from 0 (impossible) to 1 (certain). Core concepts include:

- **Empirical Probability:** Based on observed frequencies (e.g., flipping a coin 100 times).
- **Theoretical Probability:** Derived from the possible outcomes (e.g., probability of rolling a "6" on a fair die).
- **Conditional Probability:** The probability of an event occurring given that another event has already occurred (e.g., probability of rain given that the sky is cloudy).
- **Independent and Dependent Events:** Understanding how the occurrence of one event affects the probability of another.

Solved Problem 1: A bag contains 3 red marbles and 2 blue marbles. What is the probability of drawing a red marble? *(Solution):* Total marbles = 5. Red marbles = 3. Probability = $3/5 = 0.6$

Solved Problems in Probability Distributions

Probability distributions describe the possible outcomes of a random variable and their probabilities.

- **Normal Distribution:** A bell-shaped curve, common in many natural phenomena (e.g., heights, weights).
- **Binomial Distribution:** Used for the probability of a certain number of successes in a fixed number of trials (e.g., flipping a coin 10 times and counting the number of heads).
- **Poisson Distribution:** Describes the probability of a given number of events occurring in a fixed interval of time or space (e.g., number of customers arriving at a store per hour).

Solved Problem 3: The average number of emails received per hour is 5. What is the probability of receiving exactly 3 emails in an hour? *(Solution):* Use the Poisson probability formula. (Refer to a Poisson table or calculator for the calculation).

Applications of Probability and Statistics

- **Hypothesis Testing:** A statistical procedure used to determine whether there is enough evidence in the data to support a particular claim about a population.
- **Regression Analysis:** A statistical method used to model the relationship between a dependent variable and one or more independent variables.
- **Confidence Intervals:** A range of values that likely contains the true value of a population parameter.

Solved Problem 4: A company wants to determine if a new training program improves employee performance. **(Solution):** Design an experiment to collect data, calculate the mean performance score before and after training, and use appropriate statistical tests.

Foundational Concepts: Probability Solved Problems

Before we can analyze data, we need to understand the likelihood of events occurring. This is where probability theory comes in.

Basic Probability: The Coin Toss and Beyond

The simplest scenarios often involve equally likely outcomes. Think about flipping a fair coin:

Problem 1: What is the probability of getting heads when flipping a fair coin?

Solution:

1. The total number of possible outcomes is 2 (Heads or Tails).
2. The number of favorable outcomes (getting heads) is 1.
3. The probability of an event is calculated as: (Number of favorable outcomes) / (Total number of possible outcomes).
4. Therefore, $P(\text{Heads}) = 1 / 2 = 0.5$ or 50%.

Problem 2: A standard six-sided die is rolled. What is the probability of rolling a 4?

Solution:

1. Total possible outcomes = 6 (1, 2, 3, 4, 5, 6).
2. Favorable outcome = 1 (rolling a 4).
3. $P(\text{Rolling a 4}) = 1 / 6$.

These examples illustrate the fundamental principle of calculating probability when all outcomes are equally likely. This basic understanding is crucial for more complex probability calculations.

Compound Events: AND and OR

What happens when we consider multiple events? We need to understand how probabilities combine.

Problem 3: What is the probability of rolling a 3 and then a 5 on two consecutive rolls of a fair six-sided die?

Solution:

1. These are independent events, meaning the outcome of the first roll doesn't affect the second.
2. $P(\text{Rolling a 3 on the first roll}) = 1/6$.
3. $P(\text{Rolling a 5 on the second roll}) = 1/6$.
4. For independent events, the probability of both occurring is the product of their individual probabilities: $P(A \text{ and } B) = P(A) * P(B)$.
5. $P(\text{Rolling a 3 and then a 5}) = (1/6) * (1/6) = 1/36$.

Problem 4: A bag contains 5 red balls and 3 blue balls. If you draw one ball at random, what is the probability of drawing a red ball OR a blue ball?

Solution:

1. Total balls = $5 + 3 = 8$.
2. $P(\text{Red}) = 5/8$.
3. $P(\text{Blue}) = 3/8$.
4. Since drawing a red ball and drawing a blue ball are mutually exclusive events (you can't draw both at once), we add their probabilities: $P(A \text{ or } B) = P(A) + P(B)$.
5. $P(\text{Red or Blue}) = 5/8 + 3/8 = 8/8 = 1$.
6. This makes sense, as you are guaranteed to draw either a red or a blue ball.

Conditional Probability: "Given That..."

Conditional probability deals with the likelihood of an event occurring given that another event has already occurred. This is a cornerstone of statistical modeling.

Problem 5: In a class of 30 students, 15 students like Math, 10 students like Science, and 5 students like both Math and Science. If you randomly select a student, what is the probability that they like Science GIVEN that they like Math?

Solution:

1. Let M be the event that a student likes Math.
2. Let S be the event that a student likes Science.
3. We are given: $|M| = 15$, $|S| = 10$, $|M \cap S| = 5$, Total students = 30.
4. We want to find $P(S | M)$, the probability of liking Science given that they like Math.
5. The formula for conditional probability is: $P(S | M) = P(S \cap M) / P(M)$.
6. First, let's find the probabilities:
7. $P(S \cap M) = (\text{Number of students who like both}) / (\text{Total students}) = 5 / 30$.
8. $P(M) = (\text{Number of students who like Math}) / (\text{Total students}) = 15 / 30$.
9. Now, apply the formula: $P(S | M) = (5/30) / (15/30) = 5 / 15 = 1/3$.
10. Alternatively, we can think of it this way: We know the student likes Math, so our new sample space is only those who like Math (15 students). Out of these 15, 5 also like Science. So, the probability is $5/15 = 1/3$.

Conditional probability is vital for understanding dependencies between variables, a key aspect of **statistical analysis** and **data interpretation**.

Introduction to Statistics: Descriptive Statistics Solved Problems

Once we have data, statistics helps us summarize and describe it. This is descriptive statistics.

Measures of Central Tendency: Mean, Median, and Mode

These measures tell us about the "center" of a dataset.

Problem 6: Calculate the mean, median, and mode for the following set of scores: {7, 8, 9, 7, 6, 8, 7, 10}

Solution:

1. **Mean (Average):** Sum of all values / Number of values.
2. $\text{Sum} = 7 + 8 + 9 + 7 + 6 + 8 + 7 + 10 = 62$.
3. Number of values = 8.
4. $\text{Mean} = 62 / 8 = 7.75$.
5. **Median (Middle Value):** First, order the data: {6, 7, 7, 7, 8, 8, 9, 10}.
6. Since there are an even number of values (8), the median is the average of the two middle values (the 4th and 5th values).
7. $\text{Median} = (7 + 8) / 2 = 7.5$.
8. **Mode (Most Frequent Value):** The number that appears most often.
9. The number 7 appears 3 times, which is more than any other number.
10. Mode = 7.

Understanding these central tendency measures helps in summarizing **data sets** and getting a quick sense of typical values.

Measures of Dispersion: Range, Variance, and Standard Deviation

These measures tell us how spread out the data is.

Problem 7: Calculate the range, variance, and standard deviation for the scores: {7, 8, 9, 7, 6, 8, 7, 10}

Solution:

1. We already have the ordered data: {6, 7, 7, 7, 8, 8, 9, 10} and the mean = 7.75.
2. **Range:** Highest value - Lowest value.
3. $\text{Range} = 10 - 6 = 4$.
4. **Variance (σ^2):** The average of the squared differences from the mean. This measures how far each number is from the mean, on average.
5. Calculate the difference of each data point from the mean, square it, and sum them up.
6. $(7 - 7.75)^2 = (-0.75)^2 = 0.5625$
7. $(8 - 7.75)^2 = (0.25)^2 = 0.0625$
8. $(9 - 7.75)^2 = (1.25)^2 = 1.5625$
9. $(7 - 7.75)^2 = (-0.75)^2 = 0.5625$
10. $(6 - 7.75)^2 = (-1.75)^2 = 3.0625$
11. $(8 - 7.75)^2 = (0.25)^2 = 0.0625$
12. $(7 - 7.75)^2 = (-0.75)^2 = 0.5625$
13. $(10 - 7.75)^2 = (2.25)^2 = 5.0625$
14. Sum of squared differences = $0.5625 + 0.0625 + 1.5625 + 0.5625 + 3.0625 + 0.0625 + 0.5625 + 5.0625 = 11.5$.
15. For a population, Variance (σ^2) = Sum of squared differences / N (number of data points) = $11.5 / 8 = 1.4375$.

16. *Note: If this were a sample, we would divide by $N-1$ (degrees of freedom), resulting in sample variance $s^2 = 11.5 / 7 \approx 1.643$.*
17. **Standard Deviation (σ):** The square root of the variance. It gives us a measure of spread in the original units of the data.
18. Standard Deviation (σ) = $\sqrt{\text{Variance}} = \sqrt{1.4375} \approx 1.199$.
19. *For sample standard deviation, $s = \sqrt{s^2} \approx \sqrt{1.643} \approx 1.282$.*

Measures of dispersion are crucial for understanding the variability within **statistical data** and are fundamental to **inferential statistics**.

Inferential Statistics: Drawing Conclusions from Data

Inferential statistics uses sample data to make generalizations and predictions about a larger population. This is where probability plays a crucial role.

Confidence Intervals: Estimating Population Parameters

A confidence interval provides a range of values that is likely to contain a population parameter (like the mean) with a certain level of confidence.

Problem 8: A survey of 100 randomly selected students found that the average study time per week is 15 hours, with a sample standard deviation of 4 hours. Construct a 95% confidence interval for the average study time of all students.

Solution:

1. We are given: Sample mean ($\bar{x}$) = 15 hours, Sample standard deviation (s) = 4 hours, Sample size (n) = 100.
2. We want a 95% confidence interval. For a large sample size ($n > 30$), we can use the z-distribution.
3. The critical z-value for a 95% confidence level is approximately 1.96 (this value corresponds to the z-scores that leave 2.5% in each tail of the standard normal distribution).
4. The formula for a confidence interval for the mean is: $\bar{x} \pm z * (s / \sqrt{n})$.
5. Calculate the margin of error: $1.96 * (4 / \sqrt{100}) = 1.96 * (4 / 10) = 1.96 * 0.4 = 0.784$.
6. The confidence interval is: 15 ± 0.784 .
7. Lower bound = $15 - 0.784 = 14.216$.
8. Upper bound = $15 + 0.784 = 15.784$.
9. Therefore, we are 95% confident that the true average study time for all students lies between 14.216 and 15.784 hours per week.

Confidence intervals are essential for making informed decisions based on limited data, widely used in **statistical inference**.

Hypothesis Testing: Making Decisions About Claims

Hypothesis testing is a formal procedure for deciding whether to reject or fail to reject a statement (hypothesis) about a population parameter.

Problem 9: A new fertilizer is claimed to increase crop yield by an average of 10 bushels per acre. A test was conducted on 50 acres, and the average yield increase was 8 bushels with a standard deviation of 5 bushels. At a significance level of 0.05, is there enough evidence to reject the claim?

Solution:

1. **Step 1: State the Hypotheses.**

2. Null Hypothesis (H_0): The average yield increase is 10 bushels per acre ($\mu = 10$).
3. Alternative Hypothesis (H_1): The average yield increase is not 10 bushels per acre ($\mu \neq 10$) – this is a two-tailed test.
4. **Step 2: Set the Significance Level.**
5. $\alpha = 0.05$.
6. **Step 3: Calculate the Test Statistic.**
7. Since $n > 30$, we use the z-test.
8. $z = (\bar{x} - \mu) / (s / \sqrt{n})$
9. $z = (8 - 10) / (5 / \sqrt{50}) = -2 / (5 / 7.07) \approx -2 / 0.707 \approx -2.83$.
10. **Step 4: Determine the Critical Value(s) or p-value.**
11. For a two-tailed test with $\alpha = 0.05$, the critical z-values are approximately ± 1.96 .
12. Alternatively, we can find the p-value associated with $z = -2.83$. Using a z-table or calculator, the p-value is approximately 0.0047.
13. **Step 5: Make a Decision.**
14. Compare the test statistic to the critical value: $-2.83 < -1.96$. (The test statistic falls in the rejection region).
15. Compare the p-value to the significance level: $0.0047 < 0.05$. (The p-value is less than α).
16. **Conclusion:** Since the test statistic falls in the rejection region (or the p-value is less than α), we reject the null hypothesis. There is sufficient statistical evidence at the 0.05 significance level to conclude that the average yield increase is not 10 bushels per acre.

Hypothesis testing is fundamental to scientific research and decision-making in many fields, including **statistical modeling** and **data analysis**.

The Cornerstone of Uncertainty: Understanding Probability

Probability theory provides the mathematical framework for quantifying uncertainty. It allows us to express the likelihood of an event occurring. Understanding the fundamental principles is crucial before diving into complex **probability and statistics solved problems**.

Basic Probability Concepts and Solved Examples

At its core, probability is the measure of the likelihood of an event. It's typically expressed as a number between 0 and 1, where 0 means the event is impossible, and 1 means it's certain.

Definition of Probability

The probability of an event A, denoted as $P(A)$, is calculated as:

$$P(A) = (\text{Number of favorable outcomes}) / (\text{Total number of possible outcomes})$$

Solved Problem 1: Rolling a Die

Problem: What is the probability of rolling a 4 on a fair six-sided die?

Solution:

1. Favorable outcome: Rolling a 4 (1 outcome)
2. Total possible outcomes: Rolling a 1, 2, 3, 4, 5, or 6 (6 outcomes)
3. $P(\text{rolling a 4}) = 1 / 6$

This simple example illustrates the foundational concept of probability. Understanding this forms the basis for more intricate **probability calculation examples**.

Compound Events and Conditional Probability

Many real-world scenarios involve multiple events happening together or one event influencing another. This is where compound and conditional probabilities become essential.

Independent vs. Dependent Events

Independent events: The occurrence of one event does not affect the probability of the other. For example, flipping a coin twice.

Dependent events: The occurrence of one event affects the probability of the other. For example, drawing two cards from a deck without replacement.

Solved Problem 2: Drawing Cards

Problem: What is the probability of drawing two Aces from a standard 52-card deck without replacement?

Solution:

1. Probability of drawing the first Ace: There are 4 Aces in a deck of 52 cards. $P(1\text{st Ace}) = 4/52$.
2. After drawing one Ace, there are 3 Aces left and 51 cards remaining in the deck.
3. Probability of drawing the second Ace, given the first was an Ace: $P(2\text{nd Ace} \mid 1\text{st Ace}) = 3/51$.
4. The probability of both events happening is the product of their probabilities:
5. $P(2 \text{ Aces}) = P(1\text{st Ace}) * P(2\text{nd Ace} \mid 1\text{st Ace}) = (4/52) * (3/51) = 12 / 2652 = 1 / 221$.

This demonstrates conditional probability and how events can be dependent, a common theme in **probability and statistics solved problems** related to real-world scenarios.

Conditional Probability Formula

$P(A|B) = P(A \text{ and } B) / P(B)$, where $P(A|B)$ is the probability of event A occurring given that event B has already occurred.

The Power of Distributions: Binomial and Normal Distributions

Probability distributions are fundamental tools for modeling the outcomes of random variables. Two of the most widely used are the binomial and normal distributions.

Binomial Distribution

The binomial distribution is used for scenarios with a fixed number of independent trials, each with two possible outcomes (success or failure), and a constant probability of success. This is a key area for **probability solved examples binomial**.

Solved Problem 3: Coin Flips

Problem: If a fair coin is flipped 10 times, what is the probability of getting exactly 7 heads?

Solution:

This follows a binomial distribution with:

1. n (number of trials) = 10
2. k (number of successes) = 7
3. p (probability of success, i.e., getting a head) = 0.5

4. q (probability of failure, i.e., getting a tail) = 0.5

The binomial probability formula is: $P(X=k) = C(n, k) \cdot p^k \cdot q^{(n-k)}$

Where $C(n, k)$ is the binomial coefficient, calculated as $n! / (k! \cdot (n-k)!)$

$$C(10, 7) = 10! / (7! \cdot 3!) = (10 \cdot 9 \cdot 8) / (3 \cdot 2 \cdot 1) = 120$$

$$P(X=7) = 120 \cdot (0.5)^7 \cdot (0.5)^3 = 120 \cdot (0.0078125) \cdot (0.125) = 0.1171875$$

So, the probability of getting exactly 7 heads in 10 coin flips is approximately 0.1172 or 11.72%.

Normal Distribution

The normal distribution, often called the bell curve, is a continuous probability distribution that is symmetric and unimodal. It's ubiquitous in nature and many statistical applications, making **normal distribution solved problems** crucial.

Solved Problem 4: IQ Scores

Problem: The IQ scores of a population are normally distributed with a mean (μ) of 100 and a standard deviation (σ) of 15. What is the probability that a randomly selected person has an IQ score greater than 130?

Solution:

We need to calculate the z-score, which standardizes the value:

$$z = (X - \mu) / \sigma$$

$$z = (130 - 100) / 15 = 30 / 15 = 2$$

Now, we look up the probability associated with a z-score of 2 in a standard normal distribution table or use statistical software. The table typically gives the probability of a value being less than or equal to the z-score, $P(Z \leq 2)$.

$$P(Z \leq 2) \approx 0.9772$$

Since we want the probability of an IQ score *greater than* 130, we subtract this from 1:

$$P(X > 130) = P(Z > 2) = 1 - P(Z \leq 2) = 1 - 0.9772 = 0.0228$$

Therefore, the probability of a randomly selected person having an IQ score greater than 130 is approximately 0.0228 or 2.28%.

The Backbone of Data Analysis: Understanding Statistics

Statistics is the science of collecting, analyzing, interpreting, presenting, and organizing data. It provides the tools to make sense of the information we gather, and **solved statistics problems** are key to mastering these tools.

Descriptive Statistics: Summarizing Data

Descriptive statistics are used to summarize and describe the main features of a dataset. This includes measures of central tendency and dispersion.

Measures of Central Tendency

Mean: The average of a dataset.

Median: The middle value of a dataset when ordered.

Mode: The most frequently occurring value in a dataset.

Solved Problem 5: Calculating Mean, Median, and Mode

Problem: Given the following dataset: {10, 12, 15, 12, 18, 20, 12, 15}. Calculate the mean, median, and mode.

Solution:

1. **Mean:** $(10 + 12 + 15 + 12 + 18 + 20 + 12 + 15) / 8 = 114 / 8 = 14.25$
2. **Median:** First, order the dataset: {10, 12, 12, 12, 15, 15, 18, 20}. Since there are 8 numbers (an even count), the median is the average of the 4th and 5th numbers: $(12 + 15) / 2 = 13.5$
3. **Mode:** The number that appears most frequently is 12 (it appears 3 times).

These basic descriptive statistics are fundamental for understanding any dataset and are often the first step in **data analysis solved problems**.

Measures of Dispersion

Range: The difference between the highest and lowest values.

Variance: The average of the squared differences from the mean.

Standard Deviation: The square root of the variance, providing a measure of spread in the original units.

Solved Problem 6: Calculating Variance and Standard Deviation

Problem: Using the dataset from Problem 5: {10, 12, 15, 12, 18, 20, 12, 15}. Calculate the variance and standard deviation.

Solution:

We already know the mean (μ) = 14.25.

Variance (σ^2):

Calculate the squared differences from the mean for each data point:

1. $(10 - 14.25)^2 = (-4.25)^2 = 18.0625$
2. $(12 - 14.25)^2 = (-2.25)^2 = 5.0625$
3. $(15 - 14.25)^2 = (0.75)^2 = 0.5625$
4. $(12 - 14.25)^2 = (-2.25)^2 = 5.0625$
5. $(18 - 14.25)^2 = (3.75)^2 = 14.0625$
6. $(20 - 14.25)^2 = (5.75)^2 = 33.0625$
7. $(12 - 14.25)^2 = (-2.25)^2 = 5.0625$
8. $(15 - 14.25)^2 = (0.75)^2 = 0.5625$

Sum of squared differences = $18.0625 + 5.0625 + 0.5625 + 5.0625 + 14.0625 + 33.0625 + 5.0625 + 0.5625 = 81.5$

Variance (for a population, σ^2) = Sum of squared differences / N = $81.5 / 8 = 10.1875$

If this were a sample, we would divide by N-1 (7), resulting in sample variance.

Standard Deviation (σ):

Standard Deviation = $\sqrt{\text{Variance}} = \sqrt{10.1875} \approx 3.19$

These measures are vital for understanding the spread and variability within data, common in **statistics problem solving**.

Inferential Statistics: Drawing Conclusions

Inferential statistics uses sample data to make generalizations or predictions about a larger population. This is where we bridge the gap between a small subset and the whole, often involving hypothesis testing and confidence intervals.

Hypothesis Testing

Hypothesis testing is a statistical method used to make decisions or judgments about a population based on sample data. It involves setting up a null hypothesis (H_0) and an alternative hypothesis (H_1).

Solved Problem 7: T-Test Example

Problem: A researcher wants to know if a new teaching method improves student test scores. They have a control group (old method) and an experimental group (new method). The mean score for the control group is 75 with a standard deviation of 8. The mean score for the experimental group is 80 with a standard deviation of 7. Both groups have 30 students. Conduct a t-test to see if there's a significant difference.

Solution:

This is a two-sample independent t-test. The goal is to test if the means of two independent groups are significantly different.

Null Hypothesis (H_0): There is no significant difference in mean scores between the two teaching methods ($\mu_1 = \mu_2$).

Alternative Hypothesis (H_1): There is a significant difference in mean scores between the two teaching methods ($\mu_1 \neq \mu_2$).

We calculate the t-statistic. The formula for the t-statistic for independent samples (assuming equal variances for simplicity, though Welch's t-test is often preferred for unequal variances) is:

$$t = (\bar{x}_1 - \bar{x}_2) / \sqrt{[s^2(1/n_1 + 1/n_2)]}$$

Where:

1. $\bar{x}_1 = 80$ (experimental group mean)
2. $\bar{x}_2 = 75$ (control group mean)
3. s^2 = pooled variance (or individual variances if not assumed equal)
4. $n_1 = 30, n_2 = 30$

Let's simplify and assume we're given the variances directly ($s_1^2=8^2, s_2^2=7^2$). For a more accurate calculation, we'd calculate pooled variance or use Welch's t-test. However, for illustration:

$$t = (80 - 75) / \sqrt{[(8^2/30) + (7^2/30)]}$$

$$t = 5 / \sqrt{[(64/30) + (49/30)]}$$

$$t = 5 / \sqrt{[(113/30)]}$$

$$t = 5 / \sqrt{[3.7667]}$$

$$t = 5 / 1.9408 \approx 2.576$$

We then compare this t-statistic to a critical value from the t-distribution table (based on degrees of freedom, which is $n_1+n_2-2 = 58$ for equal variances, and alpha level, typically 0.05). For $df=58$ and $\alpha=0.05$ (two-tailed), the critical t-value is approximately ± 2.002 .

Since our calculated t-statistic (2.576) is greater than the critical value (2.002), we reject the null hypothesis. This means there is statistically significant evidence that the new teaching method improves student test scores.

This is a classic example of **hypothesis testing solved problems**, demonstrating how we use data to support or refute claims.

Confidence Intervals

Confidence intervals provide a range of values within which the true population parameter is likely to lie, with a certain level of confidence.

Solved Problem 8: Confidence Interval for a Mean

Problem: A sample of 100 students has an average study time of 15 hours per week with a standard deviation of 3 hours. Construct a 95% confidence interval for the average study time of all students.

Solution:

We will use the formula for a confidence interval for a mean:

$$CI = \bar{x} \pm Z * (\sigma / \sqrt{n})$$

Where:

1. $\bar{x} = 15$ (sample mean)
2. $Z = 1.96$ (Z-score for 95% confidence level, from standard normal distribution table)
3. $\sigma = 3$ (sample standard deviation, often used as an estimate for population standard deviation when n is large)
4. $n = 100$ (sample size)

Calculate the margin of error:

$$\text{Margin of Error} = Z * (\sigma / \sqrt{n}) = 1.96 * (3 / \sqrt{100}) = 1.96 * (3 / 10) = 1.96 * 0.3 = 0.588$$

Construct the confidence interval:

$$CI = 15 \pm 0.588$$

$$\text{Lower bound} = 15 - 0.588 = 14.412$$

$$\text{Upper bound} = 15 + 0.588 = 15.588$$

Therefore, we are 95% confident that the true average study time for all students is between 14.412 and 15.588 hours per week. This is a key aspect of **statistics solved examples confidence interval**.

Questions & Answers About probability and statistics solved problems

No	Question	Answer
1	I'm struggling with understanding what a p-value really means in hypothesis testing. Can you give a simple, solved example?	A p-value tells you the probability of observing your data (or something more extreme) if the null hypothesis were true. Example: You're testing if a new drug lowers blood pressure. Your null hypothesis is the drug has no effect. You observe a significant drop in blood pressure. If your p-value is 0.03, it means there's only a 3% chance of seeing such a drop if the drug truly had no effect. This low probability suggests you reject the null hypothesis and conclude the drug is effective.

2	How do I determine if two variables are independent or dependent using probability?	Two events A and B are independent if the occurrence of one doesn't affect the probability of the other. Mathematically, $P(A \text{ and } B) = P(A) * P(B)$. If this equation doesn't hold, they are dependent. Example: Rolling a die twice. The outcome of the first roll doesn't affect the second. So, $P(\text{rolling a 6 on roll 1 AND rolling a 6 on roll 2}) = P(6 \text{ on roll 1}) * P(6 \text{ on roll 2}) = (1/6) * (1/6) = 1/36$. They are independent.
3	I keep hearing about 'confidence intervals'. What's a practical example of how they're used and how to interpret one?	A confidence interval provides a range of values within which a population parameter (like the mean) is likely to lie, with a certain level of confidence. Example: A pollster surveys 1000 people and estimates that 55% support a candidate, with a 95% confidence interval of (52%, 58%). This means they are 95% confident that the true proportion of supporters in the entire population falls between 52% and 58%.
4	What's the difference between combinations and permutations, and when do I use each? A quick solved problem would help!	Permutations care about the order of selection, while combinations do not. Permutations (nPr): Order matters. Combinations (nCr): Order doesn't matter. Example: How many ways can you arrange 3 books from a shelf of 5? Order matters (ABC is different from ACB), so it's a permutation: $5P3 = 5!/(5-3)! = 60$. How many ways can you *choose* 3 books from a shelf of 5 to read? Order doesn't matter, so it's a combination: $5C3 = 5!/(3!2!) = 10$.
5	I'm confused about Bayes' Theorem. Can you explain it with a relatable, solved problem?	Bayes' Theorem helps update the probability of a hypothesis based on new evidence. It's often phrased as: $P(A B) = [P(B A) * P(A)] / P(B)$. Example: You test positive for a rare disease (event B), which has a 1% prevalence ($P(A)=0.01$). The test is 99% accurate ($P(B A)=0.99$) but also has a 5% false positive rate ($P(B \text{not } A)=0.05$). Using Bayes' Theorem, you can calculate the true probability of having the disease given a positive test ($P(A B)$), which is much lower than 99% due to the low prevalence and false positives.
6	What's the intuition behind the Central Limit Theorem, and why is it so important in statistics?	The Central Limit Theorem states that the distribution of sample means will approximate a normal distribution as the sample size gets larger, regardless of the original population's distribution. This is crucial because it allows us to use normal distribution properties for inference even when we don't know the population's true shape. Example: If you repeatedly take samples of 30 coin flips and calculate the average number of heads for each sample, the distribution of those averages will be roughly bell-shaped (normal), even though a single coin flip is binary.
